Introduction to Stata

Preparation for Using Stata on Citrix

STEP 1. Use your browser to go to BC Apps on bcapps.bc.edu, login using your BC credentials, and open Stata 17SE app. For more information on troubleshooting, see https://www.bc.edu/offices/help/teaching/app_server.html

Note: There are times when too many people use Stata 17, and the system doesn't have enough licenses to add one more person; you can use Stata 16 instead in these cases.

STEP 2. To be able to store files on BC server, map the drive for BC apps storage; the detailed instructions for each operating system are available here: <u>http://www.bc.edu/offices/help/teaching/app_server/apps-files/files-map.html</u>. You have to be at BC or connect using BC VPN (<u>https://www.bc.edu/offices/help/getstarted/network/vpn.html</u>) in order to have access to BC apps storage.

Note: On Macs, you might need to repeat mapping the drive steps from time to time if BC Apps storage does not show up in a list of available folders. So keep the link and remember how to do this step for potential future use if you have a Mac.

If you run into problems, contact the BC technology help center. If they cannot resolve your issue or you need further help, please come see me.

STEP 3. Open your BC apps storage folder and create a subfolder for this class; call your subfolder socy7706.

STEP 4. Download GSS 2012 dataset from the course webpage and place it into your socy7706 subfolder in your folder on BC apps storage server.

STEP 5. Once again, go to BC Apps on bcapps.bc.edu and open Stata 17SE app, or go back to that window if it's still open. Open GSS 2012 file from inside Stata program by typing the following commands in the command line on the bottom of Stata screen (press enter after each command line):

cd "L:\socy7706\" log using stataprep.log, replace use gss2012.dta, clear log close

All of these commands should run and generate no red error messages on your Stata screen if all went well. If that's the case, you can close Stata and BC Apps once you are done.

STEP 6. Open a file explorer program and navigate to the BC Apps storage folder. Find stataprep.log file in your list and open it using any text editor. Make sure it contains a few lines of text, including your "use gss2012.dta, clear" command. Close it again.

STEP 7. Open your email, attach the stataprep.log file (make sure to navigate to the apps storage folder and then to socy7706 subfolder) and email it to yourself.

Opening data files

Download GSS 2012 dataset from the course webpage; place it into your folder on BC apps storage server. Open Stata 17SE on BCApps.

To check the current working directory, type pwd in the Command window immediately after starting Stata (without running a cd command).

. pwd L:\

Let's change the working directory for easier file access using cd (c=change d=directory) command (alternatively, you can specify the path each time, or open and save files using Stata menus):

```
. cd "L:\socy7706\"
```

Now that we have the correct working directory set up, we can open the data file from inside Stata program using the following command:

```
. use gss2012.dta, clear
```

You can also open files from the web, e.g.:

. use https://www.sarkisian.net/socy7706/gss2012.dta, clear

Keeping a record of your work

Opening the log file (we include replace option so that you don't get an error if you already used that log file name before – it will get replaced by the new one; if you want to add to the existing log, use "append" instead of "replace):

log using learn_stata.log, replace

To see the log, you can at any time press the button and view a snapshot of the log. (You can also close or suspend log using that same button.)

Two types of log -- .log and .scml. I choose .log rather than .scml type of file so it can be read in any text editor or word processor. I would recommend that you always use .log format for now. But you can also easily convert .scml type log into the text format log:

translate mylog.smcl mylog.log

You can also use translate command to recover a log when you have forgotten to start one: translate <code>@Results mylog.txt</code>

Note that if you are opening a Stata log file in a Word processor, you should change the font to a fixed width font, such as Courier New (otherwise the output looks misaligned). Courier New 10 or 9 point usually works the best. Otherwise things won't be aligned.

Basic syntax of Stata commands:

- 1. Command What do you want to do?
- 2. Names of variables, files, etc. Which variables or files do you want to use?
- 3. Qualifier on observations -- Which observations do you want to use?
- 4. Options Do you have any other preferences regarding this command?

Help and installation

Help in Stata – help and search commands:

```
. help tabulate
. search logistic
Keyword search
        Keywords: logistic

--Break--

r(1);

I used Break button to stop Stata from producing more output. If you do want to see all the output, either click on the <u>more</u> link on the bottom of the output viewer, or press space key. For some of you, more link doesn't appear and the output appears all at once rather than one page at a time. That is regulated with "set more off" and "set more on" commands in Stata (you can add perm option to make Stata remember your preference).

Using data browser to look at the data and data editor to change data: File Edit Data Graphics Statistics User Window Help

There is no UNDO button!!! That applies to all data management commands, too. But the changes are made only to the dataset that's in Stata's memory. So if you close it without saving, you can

always start again with your original dataset. If, however, you want to save your changes, you should save the data file with any changes you made – typically with a different filename:

. save gss2012changed.dta, replace file L:\socy7706\gss2012changed.dta saved

If you are not sure you want to keep your changes, use "preserve" command in the beginning to save a copy of the dataset in Stata memory; restore in the end will return the data to that saved version.

Using do-files

You should keep a do-file with all your analysis steps – that way, if you make a mistake, you can easily rerun things. To have that, we can save all the commands that we did interactively into a do-file, or we can right away write a do-file and then execute it. Open do-file editor, create and save your file (.do) – or use doedit command. You can execute that file from the do-file editor or using the command line:

. do mydofile.do

But be careful to specify the location of your file or make sure it is in the working directory specified in the last "cd" command.

It is often convenient to create and edit do-files in another text editor – in Windows, I prefer TextPad: <u>http://www.textpad.com</u>; another good option is Notepad++. For a Mac OS, you can use Sublime Text.

And if you want to save all commands you've done so far, right click on the command window and select "Save Review Contents." If some of your commands had errors (highlighted in red), you can right click on each of them and delete them from the Review window before copying. Or you can select some commands and send them to do editor by right clicking and selecting Send to Do File Editor.

You can also keep the log of just the commands: cmdlog using filename Then you can use that log as a do-file.

It's a good idea to specify Stata version in the beginning of each do file, e.g. version 17

Whether in do files or when entering commands interactively, it is useful to include comments on what you are doing: Everything typed after a star (*) or after // is treated as a comment and not executed; same with any text between /* and */

In addition, people often use /// as a line break tool to better format do-files:

```
use gss2012.dta, clear
sum age /// here I am summarizing age
wrkstat /// here I am summarizing work status, and next sex
sex
```

Note that you can't include /// on the last line of a command (or in the end of a one-line command) because otherwise it doesn't see a carriage return and doesn't execute that command at all. Use star to create comments on a separate line in such cases.

Lines in do files can be either separated with line breaks (CR=carriage return) or a delimiter ; To change, you specify the following command in the beginning of a do file. #delimit ;

To restore the carriage return delimiter inside a file, use #delimit cr. When a do-file begins execution, the delimiter is automatically set to carriage return, even if it was called from another do-file that set the delimiter to semicolon. Also, the current do-file need not worry about restoring the delimiter to what it was because Stata will do that automatically.

Closing log and exiting Stata

. log close . exit, clear

Descriptive Statistics in Stata

Let's reopen the data file and continue our log:

use gss2012.dta, clearlog using learn stata.log, append

Frequency tables -- tabulate command:

Data Management in Stata

Creating new variables: typically done using gen (often followed by replace), recode, or egen commands; egen is more advanced and we won't cover it for now, but do look at that command and its options if you are doing data management in Stata.

For example, I want to create a variable that is 0 for those people who work less than 40 hours a week and 1 for those who work 40 hours a week or more (we call this a dichotomy or a dummy variable, where 0 means absence of some characteristic and 1 means presence). Let's first examine the variable that exists in the data set:

. cod	debook hrs1								
hrs1				NUME	BER OF	HOURS	WORKED	LAST	WEEK
	type:	numeric (by	yte)						
	Tabel:	LABAD, DUL	68 nonmissing	values are	NOL I	abered			
	range: unique values:	[1,89] 68		units: missing .:	1 808/3	1,974			
	examples:	40 45							
. sur	n hrsl, det NUMBER OF	HOURS WORKEI	D LAST WEEK		-				
18	5	1							
5%	9	1							
10%	19	2	Obs	1,166	5				
25%	34	4	Sum of Wgt.	1,166	5				
50%	40		Mean	40.27358	}				
		Largest	Std. Dev.	15.54011	-				
75%	48	89							
90%	60	89	Variance	241.495	5				
95%	65	89	Skewness	.0575558	3				
99%	80	89	Kurtosis	3.649988	}				

We start by generating a new variable called hrs40 with all missing values. Then we will first fill in zeroes for those who work less than 40 hours for pay, and finally fill in 1s for those who work 40+

hours. To do so, we need to use conditions expressed as an "if" statement. To express conditions, we can use the following:

< less > more == equal <= less or equal >= more or equal ~= or != not equal

Can connect them with & (and) and | (or). Can also use parentheses to combine conditions.

So in our case, we do: . gen hrs40=. (1,974 missing values generated) . replace hrs40 = 0 if hrs1<40 (377 real changes made) . replace hrs40 = 1 if hrs1>=40 & hrs1~=. (789 real changes made) . tab hrs40, missing hrs40 | Freq. Percent Cum. 0 | 377 19.10 19.10 1 | 789 39.97 59.07 . | 808 40.93 100.00 Total | 1,974 100.00

Label the variable:

. label variable hrs40 "R works 40 hours a week or more"

Label its values: two steps, first define a set of labels, then apply this set to a variable:

. label define hrs40label 0 "less than 40" 1 "40 or more" . label values hrs40 hrs40label . tab hrs40, missing R works 40 | hours a week | or more | Freq. Percent Cum. ______ less than 40 | 377 19.10 19.10 40 or more | 789 39.97 59.07 . | 808 40.93 100.00 Total | 1,974 100.00 . codebook hrs40 _____ hrs40 R works 40 hours a week or more _____ type: numeric (float) label: hrs40label units: 1 missing .: 808/1,974 range: [0,1]
unique values: 2 tabulation: Freq. Numeric Label 377 0 less than 40 1 40 or more 789 808

To rename a variable:

. rename hrs40 hours40

There is a simpler way to generate a dummy variable that only uses one step; for example, to generate a dichotomy indicating married respondents (0=not married, 1=married):

```
. codebook marital
_____
marital
                                             MARITAL STATUS
_____
          type: numeric (byte)
          label: MARITAL
         range: [1,5]
                                units: 1
     unique values: 5
                              missing .: 0/1,974
       tabulation: Freq. Numeric Label
900 1 married
163 2 widowed
317 3 divorced
68 4 separated
                526 5 NEVER MARRIED
. gen married=(marital==1) if marital<.
. tab married
 married |
          Freq. Percent
                          Cum.
_____
     0 | 1,074 54.41 54.41
1 | 900 45.59 100.00
_____
   Total | 1,974 100.00
```

The additional condition, if marital<. , is included in order to preserve missing data – without that condition, anyone with marital variable missing would be coded as 0. Here, however, we don't have any missing values on marital status.

Another command we can use to create variables is recode command. For example, to generate marital status with 3 categories, married, previously married, never married:

Label the new variable:

. label variable marital3 "marital status 3 categories"

Label values of the new variable:

. label define marital3label 1 "married" 2 "previously married" 3 "never married"

. label values marital3 marital3label

Check the results:

. codebook marital3

marital3					marital	status	3 categories
	type: label:	numeric marital	(byte) 3label				
	range: unique values:	[1,3] 3		units: missing .:	1 0/1,974	1	
	tabulation:	Freq. 900 548 526	Numeric 1 2 3	Label married previously married never married			

These are various recoding techniques to create and deal with categorical and dichotomous variables; but recoding is also very useful for continuous variables. For example, they often have extreme values (outliers) that could impact our results unduly, and to reduce their impact, we can topcode or bottomcode the variable, that is, recode the very high or very low values to bring them more into the regular range. For example:

. tab agekdbrn, miss

R'S AGE When 1st			
CHILD BORN	Freq.	Percent	Cum.
13	+ 1	0.05	0.05
14	7	0.35	0.41
15	20	1.01	1.42
16	30	1.52	2.94
17	68	3.44	6.38
18	101	5.12	11.50
19	102	5.17	16.67
20	110	5.57	22.24
21	134	6.79	29.03
22	78	3.95	32.98
23	95	4.81	37.79
24	82	4.15	41.95
25	94	4.76	46.71
26	70	3.55	50.25
27	78	3.95	54.20
28	58	2.94	57.14
29	52	2.63	59.78
30	55	2.79	62.56
31	32	1.62	64.18
32	32	1.62	65.81
33	28	1.42	67.22
34	29	1.47	68.69
35	21	1.06	69.76
36	13	0.66	70.42
37	11	0.56	70.97
38	10	0.51	71.48
39	7	0.35	71.83
40	6	0.30	72.14
41	3	0.15	72.29
42	1	0.05	72.34
46	1	0.05	72.39
50	1	0.05	72.44
	544	27.56	100.00
Total	1,974	100.00	

There are many missing values here as well; those are people without children. The extreme values are probably legitimate values, but in many cases, if using this variable, you might still want to

bottomcode and topcode it (i.e., assign all values below 13 to have the value of 13 and all values above 44, you would assign value 44) in order to avoid the undue influence of extreme values on your results. Here, I will be generating a top-coded and bottom-coded version of agekdbrn; only the most extreme outliers (<1% of distribution) are typically top and bottom coded:

```
. . gen agekdbrn_tb=clip(agekdbrn, 13, 44)
(544 missing values generated)
. sum agekdbrn_tb
    Variable | Obs Mean Std. Dev. Min Max
    agekdbrn_tb | 1,430 24.07413 5.589537 13 44
. gen agekdbrn_t=clip(agekdbrn, ., 44)
(544 missing values generated)
. sum agekdbrn_t
    Variable | Obs Mean Std. Dev. Min Max
    agekdbrn_t | 1,430 24.07413 5.589537 13 44
```

Note that missing values are still coded as missing, they are not topcoded into the top value.

You can also create new variables by transforming existing continuous variables. The mathematical operators can be used: addition +, subtraction -, multiplication *, division /, and powers ^. You can also use parentheses when calculations are complex and the order of operations matters.

```
Age squared:
. gen age2=age^2
(5 missing values generated)
```

Square root of age:

. gen agesqrt=sqrt(age) (5 missing values generated)

```
Log of age:
. gen agelg=log(age)
(5 missing values generated)
```

Saving the dataset with the newly created variables: . save gss2012_2.dta file L:\socy7706\gss2012_2.dta saved

Entering your own data

We can do that in data editor, but we need to clear the memory first: clear all

Then you can open the editor and start entering numbers. If you have variables that contain text, you can just enter text; the resulting variables will be non-numeric (string). If, however, that text only includes a few categories, then you should assign numbers to those categories and enter numbers. For example, if you have a variable "year in college," don't type "junior" or "senior" but enter numbers 1, 2, 3, or 4 and then label the values using label define and label values commands, as discussed above.

In addition to entering the data themselves, you should also name the variables either in the Variables window (bottom right) or using commands, e.g.

rename var1 income

When done, save the new dataset:

```
. save enter_example.dta file L:\socy7706\enter_example.dta saved
```

Graphics in Stata

```
. scatter hrs1 prestg80
. graph matrix hrs1 hrs2 prestg80 sphrs1 sppres80
. graph bar, over(class) blabel(bar)
. histogram hrs1, normal
(bin=32, start=1, width=2.75)
```

We can save graphs for future use (in Stata-specific graph format; can only be opened in Stata): graph save mygraph.gph

To then display that graph, we type: graph use mygraph.gph

You can also export them into different, non-Stata formats:

. graph export mygraph.wmf, replace

The output format is determined by the suffix of the file name (see help graph export):

suffix	option	Output format
.ps	as(ps)	PostScript
.eps	as(eps)	EPS (Encapsulated PostScript)
.wmf	as(wmf)	Windows Metafile
.emf	as(emf)	Windows Enhanced Metafile
.pdf	as(pdf)	PDF
.png	as(png)	PNG (Portable Network Graphics)
.tif	as(tif)	TIFF

WMF works best for Windows computers, PNG works best for Macs.

You can also edit graphs in interactive mode using Graph Editor in Stata; however, I would recommend using options to generate the graphs you need because that allows for reproduceability. There is, however, also an option to use Recorder together with Graph Editor – it's not quite the same level of reproducibility and readability as using syntax, but at least then you can reapply all the changes to another graph (or another version of the same graph) – after starting Graph Editor, press Record prior to editing the graph, then press stop when you are done and give your recording a name:

📙 Gi	raph - Grap	h							
File	Edit C)bject	Graph	Tools	Help

	Recording n	ame:							_
	myrecord								
4									
4	Browse.				Sa	ive		Cancel	*
	A			A .		4	A A	A	

You can then create another graph and apply a recording to it:

. scatter hrs1 occ80, play(myrecord)

To further explore the options available for graphics, use: . help graph

Stata versions and settings

There are different versions of Stata: Variable number limits are 2,047 for Stata/IC, and 99 for Small Stata. When using Stata/MP and Stata/SE, the maximum number of variables in your dataset can be changed by using "set maxvar" command. The default value of maxvar is 5,000 for Stata/MP and Stata/SE. Here, we are using Stata/IC; the version on the apps server is Stata/SE.

Besides set maxvar, to make it easier for you to work with Stata, you can change some of other default settings using "set" command, e.g.:

```
set logtype text
set more off
```

Some Stata settings can be made "permanent" -- for example, if you want Stata to never pause output with a --more-- in the Results window, you could type . set more off, perm

Another useful set command that you will likely encounter once you start running statistical models on large data is "set matsize" (can also be used with "permanently" option). set matsize sets the maximum number of rows/columns that can be placed in a matrix used by Stata's data analysis commands.

For Stata/IC, the initial value is 400, but it may be changed upward or downward. The upper limit is 800. For Stata/MP and Stata/SE, the default value is 400, but it may be changed upward or downward. The upper limit is 11,000. This command may not be used with Small Stata; matsize is permanently frozen at 100.

Another useful set command has to do with graphs. . set scheme schemename [, permanently]

set scheme allows you to set the graphics scheme to be used. The default setting is s2color. You can use point and click to explore graphics schemes.
